Supplemental Map Information (User Report)

Project ID: R05Y12P10_R5_Refuge_National_Back_Bay

Project Title or Area: Back Water National Wildlife Refuge

Photo-interpretation: Conservation Management Institute (Contractor)

Personnel: Brian Diggs, Nicole Fuhrman, Jason Herman, Scott Klopfer, Kevin McGuckin, David Orndorff– Conservation Management Institute at Virginia Tech in Blacksburg, VA

Source Imagery (type, scale and date):
True Color, 1 meter, 2009 National Agriculture Imagery Program (NAIP)

Collected from the United States Department of Agriculture (USDA):
http://datagateway.nrcs.usda.gov/

Date Started: 06/15/2009
Date Completed: 01/12/2012
Number of 24k quads: 4

Collateral Data (include any digital data used as collateral): Data from the North Carolina Submerged Aquatic Vegetation Mapping Project (NCSAV), SSURGO hydric soils, NRCS Digital Raster Graphic (DRG), USGS National Elevation Dataset (NED) 10 meter, and most recent CIR imagery where available.

NCSAV from: http://portal.ncdenr.org/web/apnep/sav-resources

All other data collected from: http://datagateway.nrcs.usda.gov/

Inventory Method (original mapping, map update, techniques used): The NWI update for Back Bay National Wildlife Refuge was created with the 2009 NAIP imagery. Polygons were created using heads-up digitization. Wetlands were identified at a maximum zoom scale of 1:12,000 and delineated at approximately 1:8,000. Older NWI datasets were used to identify additional wetland locations. Special modifiers were added to describe disturbed and altered wetlands and deepwater habitats: ditching, impoundment, spoil deposition, excavation, artificial water control.

Where available, the NWI updates used data directly from the NCSAV layer and incorporated into the larger wetland dataset. Cowardin codes were added when incorporating the NCSAV data. We also used the following ancillary datasets to help further wetland interpretation: SSURGO hydric soils, DRG contours, NED, and CIR imagery.

Classification (Cowardin wetlands, riparian, uplands, hydrogeomorphic, etc.): We used the Cowardin *et al.* (1979) system for wetlands and deepwater habitats.

Data Limitations: None

General description of the Project Area: Atlantic and Gulf Coastal Plains, Florida, 173,800 mi2 (450,100 km2)

Land-surface form.--This province comprises the flat and irregular Atlantic and Gulf Coastal Plains down to the sea. Well over 50 percent of the area is gently sloping. Local relief is less than 300 ft (90 m), although some areas are gently rolling. Most of the region's numerous streams are sluggish; marshes, swamps, and lakes are numerous.

Climate.--The climate regime is equable, with a small to moderate annual temperature range. Average annual temperature is 60 to 70F (16 to 21C). Rainfall is abundant and well distributed throughout the year; precipitation ranges from 40 to 60 in (1,020 to 1,530 mm) per year.

Vegetation.--Temperate rainforest, also called temperate evergreen forest or laurel forest, is typical in this province. Temperate rainforest has fewer species of trees than its equatorial or tropical counterparts, and hence larger populations of individual species. Trees are not as tall here as in low-latitude rainforests; leaves are usually smaller and more leathery, and the leaf canopy less dense. Common species include evergreen oaks and members of the laurel and magnolia families. There is usually a well-developed lower stratum of vegetation that may variously include tree ferns, small palms, shrubs, and herbaceous plants. Lianas and epiphytes are abundant. At higher elevations, where fog and clouds persist, the trunks and branches of trees are often sheathed in moss. A striking example of epiphyte accumulation at lower elevations is the Spanish "moss" that festoons the Evangeline oak, baldcypress, and other trees of the eastern Gulf coast.

Along the Atlantic coast, the extensive coastal marshes and interior swamps are dominated by gum and cypress. Most upland areas are covered by subclimax pine forest, which has an understory of grasses and sedges called savannas. Undrained shallow depressions in savannas form upland bogs or pocosins, in which evergreen shrubs predominate.

A word about the vegetation of the coastal Southeastern United States may prevent some misunderstanding. On forest maps of the United States and on numerous maps of world vegetation, this coastal zone is shown as having needleleaf evergreen or coniferous forest. It is true that sandy uplands have forests of loblolly and slash pine, and that baldcypress is a dominant tree in swamps; but such vegetation represents either xerophytic and hydrophytic forms in excessively dry or wet habitats, or second-growth forest following fire and deforestation. The climax vegetation of mesophytic habitats is the evergreen-oak and magnolia forest.

Soils.--Soils are mainly Ultisols, Spodosols, and Entisols. Temperate rainforest grows on a wide variety of upland soils, but most tend to be wet, acidic, and low in major plant nutrients. The soils are derived mainly from coastal plain sediments ranging from heavy clay to gravel, with sandy materials predominant. Silty soils occur mainly on level expanses. Sands are prevalent in hilly areas, but they also cover broad flats in central Florida.

Fauna.--This region provides habitat for a wide variety of animals. Except for a few isolated areas where black bear or the endangered Florida panther are found in small numbers, the whitetail deer is the only large indigenous mammal. Common small mammals include raccoons, opossums, flying squirrels, rabbits, and numerous species of ground-dwelling rodents.

Bobwhite and wild turkey are the principal game birds. Migratory nongame bird species are numerous, as are migratory waterfowl. Winter birds are are diverse and numerous. The red-cockaded woodpecker is an endangered species.

Of the numerous species of reptiles found in this province, the American alligator is the largest.
